Chlamydia
Looking after your sexual health
Chlamydia is one of the most common sexually transmitted infections (STIs). It is very easy to treat and cure. Up to one in ten sexually active young people are thought to have chlamydia. If left untreated it can cause painful complications and serious health problems such as infertility. This booklet gives you information about chlamydia, what you can do if you are worried that you might have the infection and advice on how to protect yourself.

What causes chlamydia?
Chlamydia trachomatis is a bacteria, which is found in the semen and vaginal fluids of men and women who have the infection. Chlamydia is easily passed from one person to another through sexual contact. Anyone who is sexually active can get it and pass it on. You don’t need to have lots of sexual partners.

How is chlamydia passed on?
Chlamydia is usually passed from one person to another during sex. You can become infected with chlamydia if you come into contact with the semen or vaginal fluids of someone who already has the infection.

The bacteria can live inside the cells of the cervix (entrance to the uterus – womb), the urethra (tube where urine comes out), the rectum (back passage) and sometimes the throat and eyes.
The infection is most commonly spread through:
- unprotected vaginal, anal or oral sex
- sharing sex toys if you don’t wash them or cover
  them with a new condom each time they’re used.

Infected semen or vaginal fluid coming into contact
with the eye can cause conjunctivitis.

Chlamydia can also be passed from a pregnant
woman to her baby (see page 13).

It is not yet clear if chlamydia can be spread
by transferring infected semen or vaginal fluid to
another person’s genitals on the fingers or through
rubbing vulvas (female genitals) together.

You cannot catch chlamydia from kissing,
hugging, sharing baths or towels, swimming pools,
toilet seats or from sharing cups, plates or cutlery.

What are the signs and symptoms?
About 70 per cent of infected women and 50
per cent of men will not have any obvious signs
or symptoms or they may be so mild they are
not noticed.

Signs and symptoms can show up 1–3 weeks
after coming into contact with chlamydia, many
months later, or not until the infection spreads
to other parts of your body. You might notice:

Women
- bleeding between periods and/or heavier periods
  (including women who are using hormonal
  contraception)
- bleeding after sex
- pain and/or bleeding when you have sex
- lower abdominal pain (pelvic pain)
- an unusual vaginal discharge
- pain when passing urine
Men
- a white/cloudy or watery discharge from the tip of the penis
- pain when passing urine
- possible pain in the testicles.

Men and women
There are rarely any symptoms if the infection is in the rectum but it may cause discomfort and discharge.

Infection in the eyes can cause pain, swelling, irritation and discharge (conjunctivitis).

Infection in the throat is uncommon and usually has no symptoms.

How will I know if I have the infection?
You can only be certain you have chlamydia if you have a test so don’t delay in getting a check-up.

The National Chlamydia Screening Programme in England shows that risk factors for chlamydia increase if you are under 25, have a new sexual partner, or more than one sexual partner in the last year, and have not used condoms.

You may wish to have a test if:
- you, or a partner, have or think you might have symptoms
- you have recently had unprotected sex with a new partner
- you, or a partner, have had unprotected sex with other partners
- during a vaginal examination your doctor or nurse says that the cells of the cervix are inflamed or there is a discharge
- a sexual partner tells you they have a sexually transmitted infection
- you have another sexually transmitted infection
- you are pregnant or planning a pregnancy.
You could still have chlamydia even if a partner has tested negative – you cannot always rely on a partner's negative test result.

If you have chlamydia you may wish to be tested for other sexually transmitted infections as you can have more than one sexually transmitted infection at the same time.

**How soon after sex can I have a check-up?**

It is important not to delay going for a check-up if you think you might have chlamydia. A test can be carried out straightaway but you may be advised to have another test two weeks after having sex. You can have a test for chlamydia even if there are no symptoms.

**What does the check-up involve?**

**Women**
- You may be asked to use a swab or a tampon yourself to collect cells from inside the vagina.
- A doctor or nurse may use a swab to collect a sample of cells from the cervix during an internal examination, or from the vagina.

**Men and women**
- You may be asked to provide a urine sample (this is usually the test offered to men). Before having this test you may be advised not to pass urine for 1–2 hours.
- A doctor or nurse may use a swab to collect a sample of cells from the entrance of the urethra.
- If you have had anal or oral sex the doctor or nurse may use a swab to collect cells from your rectum and throat. These swabs are not done routinely.
- If you have conjunctivitis symptoms – discharge
from the eye(s) - swabs will also be used to collect cells from your eye(s).

A swab looks a bit like a cotton bud but is smaller and rounded. It is wiped over the parts of the body that could be infected and easily picks up samples of discharge and cells. This only takes a few seconds and is not painful, though it may be uncomfortable for a moment.

Cervical screening tests and routine blood tests do not detect chlamydia. If you are not sure whether you have been tested for chlamydia, just ask.

How accurate are the tests?
The accuracy of a chlamydia test depends on the kind of test used and the type of sample that is collected. The recommended tests are over 90 per cent accurate in picking up the infection. As no test is 100 per cent accurate there is a small chance that the test will give a negative result when you do have the infection. This is known as a false negative result. This can sometimes explain why you might get a different result when you go to a different clinic to have another test or why you and a partner might get a different test result.

It is possible for the test to be positive if you haven’t got chlamydia, but this is rare.

Where can I get a check-up?
There are a number of services you can go to. Choose the service you feel most comfortable with. A chlamydia test can be done at:
- a genitourinary medicine (GUM) or sexual health clinic
- your general practice
- contraception and young people’s clinics.
For information on how to find a service see Helplines and websites on the back cover.

Abortion clinics, antenatal services and some gynaecology services may also offer women a test.

In addition, The National Chlamydia Screening Programme in England offers free tests to men and women under 25 who have ever been sexually active. Under this programme, tests are also available from places such as colleges, youth clubs, military bases, some pharmacies and other places which are convenient for young people to use. The screening programme is usually advertised locally.

It is possible to buy a chlamydia test to do at home. The accuracy of these tests varies. Some types are very accurate when carried out according to the instructions, others can be less reliable. If you buy a self-testing kit make sure you get advice from the pharmacist or your doctor.

You can also choose to pay for a chlamydia test at a private clinic.

Will I have to pay for tests and treatment?
All tests are free through NHS services and the National Chlamydia Screening Programme. Treatment is also free but if you go to your general practice you may have to pay a prescription charge for treatment.

What is the treatment for chlamydia?
The common treatment for chlamydia is a course of antibiotics which, if you take it according to the instructions, is at least 95 per cent effective.

- Treatment of chlamydia involves taking a course of antibiotic tablets either as a single dose or a longer course (up to two weeks).
• If there is a high chance you have the infection, treatment may be started before the results of the test are back. You will always be given treatment if your partner is found to have chlamydia.
• You may also need other treatment if complications have occurred.
• Do tell the doctor or nurse if you are pregnant, or think you might be, or you are breastfeeding. This will affect the type of antibiotic that you are given.
• There is currently no evidence that complementary therapies can cure chlamydia.

**When will the signs and symptoms go away?**
You should notice an improvement in the signs and symptoms quite quickly.
• Discharge or pain when you urinate should improve within a week.
• Bleeding between periods or heavier periods should improve by your next period.
• Pelvic pain and pain in the testicles should start to improve quickly but may take up to two weeks to go away.

If you have pelvic pain or painful sex that does not improve see your doctor or nurse as it may be necessary to have some further treatment or investigate other possible causes of the pain.
Do I need to have a test to check that the chlamydia has gone?

If you take the treatment according to the instructions you will not normally need a follow-up test. However, you should go back to the clinic if:

- you think you may have come into contact with chlamydia again
- you had unprotected sex with a partner before the treatment was finished (see How soon can I have sex again? on page 11).
- you did not complete the treatment or did not take it according to the instructions
- the signs and symptoms don’t go away (see When will the signs and symptoms go away? on page 9)
- your test was negative but you develop signs or symptoms of chlamydia (see What are the signs and symptoms? on page 4).

In these situations you may need a repeat test (which can be done 5–6 weeks after the first test). You may need another course of antibiotics.

If you were treated for chlamydia in pregnancy you may be advised to have another test.

You can always go back to the doctor, nurse or clinic if you have any questions or need any advice on how to protect yourself from infection in the future.

What happens if chlamydia isn’t treated?

If chlamydia is treated early it is unlikely to cause any long-term problems. Not everyone who has chlamydia has complications. However, without proper treatment the infection can spread to other parts of the body. The more times you have chlamydia the more likely you are to get
complications.
- In women, chlamydia can spread to other reproductive organs causing pelvic inflammatory disease (PID). This can lead to long-term pelvic pain, blocked fallopian tubes, infertility and ectopic pregnancy (when the pregnancy develops outside the uterus, usually in a fallopian tube). In women, chlamydia can also spread to the liver causing pain and inflammation. This usually gets better with the correct antibiotic treatment.
- In men, chlamydia can lead to infection in the testicles and possibly reduce fertility.
- Rarely, chlamydia can lead to inflammation of the joints in both men and women. This is known as reactive arthritis and it is sometimes accompanied by inflammation of the urethra and the eye when it is known as Reiter's Syndrome. This is more likely to occur in men than women.

Can chlamydia go away without treatment?
It can but it is unlikely. If you delay seeking treatment you risk the infection causing long-term damage and you may still be able to pass the infection on to someone else.

How soon can I have sex again?
Do not have oral, vaginal or anal sex, or use sex toys, until seven days after you and your partner have both finished the treatment and any symptoms have gone. This is to help prevent you being re-infected or passing the infection on to someone else. If you are given antibiotic treatment called azithromycin that you take for only one day you will need to avoid sex for seven days after you have taken the tablets.
