Genital warts

Looking after your sexual health
Genital warts

Genital warts are the most common viral sexually transmitted infection (STI). They are caused by the human papilloma virus (HPV) which can be passed on during sexual contact. Not everyone who has the virus develops genital warts. For most people, including those who have visible warts, the virus will be cleared from the body over time. It is rare for genital warts to cause any long-term health problems.

This booklet gives you information about genital warts, what you can do if you are worried that you might have HPV infection and advice on how to protect yourself.

What causes genital warts?

Genital warts are caused by an infection of the skin of the genital and anal area with the human papilloma virus (HPV).

There are over 100 different types of HPV which can affect different parts of the body, including the hands and feet (a wart on the foot is called a verruca). Approximately 30 types of HPV can live in and around the genital and anal areas but most genital warts are caused by just two types of virus (types 6 and 11).
How are genital warts passed on?
The virus that causes genital warts is easily passed from one person to another through sexual contact. Anyone who is sexually active can get the virus. Both men and women can have the virus, and pass it on:

- Genital warts can spread from one person to another during vaginal or anal sex.
- The virus can be spread by skin to skin contact so it can be passed on by close genital contact – you don’t need to have penetrative sex (vaginal or anal) to pass it on.
- The virus will not pass through a condom but as condoms do not cover all of the genital area it is possible to infect genital skin that is not covered by the condom.
- The virus is most likely to be passed on when warts are present but it is still possible to pass the virus on after warts have disappeared.
- It is possible, but very rare, to develop warts in the mouth or throat, or on the lips from oral sex.
- Warts can spread from the genital area to the area around the anus without having anal sex.
- It is possible for warts on the hand to be passed to the genitals, but this is very rare.
- It is possible for a pregnant woman who has genital warts at the time to pass the virus to her baby at birth, but this is rare.
- You cannot get genital warts from kissing, hugging, sharing baths or towels, from swimming pools, toilet seats or from sharing cups, plates or cutlery.
What are the signs and symptoms?
Most people with HPV infection will not develop visible warts and the virus will go away on its own. This means you may not know whether you or your partner have the virus.

If warts do appear, this can happen from three weeks to many months or even years, after coming into contact with the virus. You might notice small, fleshy growths, bumps or skin changes which may appear anywhere in or on the genital or anal area.

- In women, warts can be found on the vulva (the lips around the opening to the vagina), cervix (entrance to the uterus (womb) and upper thighs, in the vagina and on or inside the anus.
- In men, warts can be found on the penis, scrotum, urethra (tube where urine comes out) and the upper thighs, and on or inside the anus.
- You might see or feel them, or your partner might notice them. Often they are so tiny, or so difficult to see, that you don’t even know you have them.
- They can be flat or smooth small bumps or quite large, pink, cauliflower-like lumps.
- Warts can appear on their own or in groups.
- Genital warts are usually painless but may occasionally itch and cause some inflammation.
- They may cause bleeding from the anus or the urethra.
- If your flow of urine is distorted this may be a sign of warts in the urethra.
How will I know if I have the virus?
You can usually only be certain you have genital warts if the doctor or nurse looks at the warts and confirms you have the infection. Even if you or your partner feel sure you have genital warts, it is still advisable to have a check-up to confirm this.

You could still have genital warts even if your partner doesn't have any visible warts.
It is possible to have more than one sexually transmitted infection at the same time. You may wish to have a check-up for infection if:
- you, or your partner have, or think you might have, symptoms
- you have recently had unprotected sex with a new partner
- you, or your partner, have had unprotected sex with other partners
- a sexual partner tells you they have a sexually transmitted infection
- you have another sexually transmitted infection
- you are pregnant or planning a pregnancy.

How soon after sex can I be checked for genital warts?
You can be checked as soon as you think you might have been in contact with the virus. As visible warts don't always develop straightaway, you will be advised on how to check yourself for any warts that develop and what to do if you notice any.

What does the check-up involve?
The main check for genital warts is for the doctor or nurse to look at the warts. They may do this using a magnifying lens.
You may also need an internal examination of the vagina or anus to see if there are any warts inside.

Very rarely it is necessary to take a small sample (biopsy) of the wart for closer examination. Depending on the area being examined, local anaesthetic may be used.

There are new tests that look for some types of the virus itself but these are not used as a routine test for genital warts.

There is no blood test for the wart virus.

**How accurate is the check-up?**

Most warts are easily diagnosed by looking at them.

**Where can I get a check-up?**

There are a number of services you can go to. Choose the service you feel most comfortable with. A genital warts check-up can be done at:

- a genitourinary medicine (GUM) or sexual health clinic
- some general practices; ask a doctor or practice nurse
- some contraception clinics and young people’s services.

For information on how to find a service see Helplines and websites on the back cover.

**Will I have to pay for the check-up and treatment?**

All tests are free through NHS services. Treatment is also free unless you go to your general practice when you may have to pay a prescription charge for the treatment.
What is the treatment for genital warts?

You will only be offered treatment if you have visible warts. The treatment will depend on what the warts look like, how many you have and where they are. The aim of treatment is to remove visible warts. How effective the treatment is varies and depends on the size and type of warts, the treatment that is used and how good your immune system is at fighting the virus.

Some people do not need treatment, or they choose not to have any. However, for most people, having treatment is likely to make the warts go away more quickly. As genital warts are caused by a virus and not bacteria, antibiotics will not get rid of warts.

Visible warts can be removed by:

• Putting cream or a liquid onto the warts (for a few days each week). This can usually be done by yourself at home. Some people ask a partner to apply the cream or liquid for them. You may have to apply this treatment for a number of weeks.

• Freezing (cryotherapy).

• Heat (electrocautery), using local anaesthetic.

• Surgery, using local anaesthetic.

• Laser treatment, using local anaesthetic.

Some creams can weaken latex condoms, diaphragms and caps. Polyurethane types can be safely used. Ask the doctor or nurse for advice.

Sometimes more than one treatment is used at the same time. These treatments may be uncomfortable, but they are not usually painful. Treatments can cause irritation and soreness for a couple of days, so the doctor may recommend
you use some pain relieving drugs.
- Avoid perfumed soap, bath oils, bubble baths, creams and lotions until treatment is completed as these may irritate the skin.
- Tell the doctor or nurse if you are pregnant, or think you might be, as this may affect the type of treatment you are given.
- Wart treatments sold at the pharmacy are not suitable for genital warts.
- There is no evidence that complementary therapies can cure genital warts.

How quickly will the warts go away?
In some people the warts go away quickly but for others the warts are stubborn and treatment may have to be repeated a number of times. It can also take a while for the treatment to start working. Evidence suggests that smokers respond less well to treatment than non-smokers. If the first treatment doesn’t work, another treatment, or a combination of treatments, may be tried. Sometimes the warts come back (see Will the warts come back? on page 10).

Do I need to have a check-up to see if the warts have gone?
If you are having treatment for the warts at a clinic or general practice it is important to return regularly for treatment. This is so that the doctor or nurse can check that the treatments are working or advise any change of treatment. Many clinics do not ask you to return if you think the warts have cleared up. They will always be happy to see you if you want advice or to be checked.
